

You've been practicing planning a web page layout for a small business and you have to make sure that your semantic tags are set up correctly for search engines and accessibility software. You have a menu with links that lead to other parts of the website. What tag do you use to set this menu with links up?

`<nav>`

Links are best placed in the navigation tag. People look for navigation menus near the top of a page so it makes sense to place them there.

You're creating a web page and you need to split the main element into two columns so you can post two blog posts on there. Which element should you use for the columns?

Using the article element to represent each column ensures that the content of each column will be self-contained like you want a blog post to be.

You're working your project and the contents of the article element is appearing too close to the left-hand right edges of the element. What changes should be made to the CSS to improve this?

You add padding-left and padding-right CSS properties with their value set to 1 rem so that the contents will not be close to the border of the elements.
